Crucial word

## ABSTRACT

Let  $k \geq 2$  be an integer. An *abelian  $k$ th power* is a word of the form  $X_1X_2 \cdots X_k$  where  $X_i$  is a permutation of  $X_1$  for  $2 \leq i \leq k$ . A word  $W$  is said to be *crucial* with respect to abelian  $k$ th powers if  $W$  avoids abelian  $k$ th powers, but  $Wx$  ends with an abelian  $k$ th power for any letter  $x$  occurring in  $W$ .

Evdokimov and Kitaev (2004) [2] have shown that the shortest length of a crucial word on  $n$  letters avoiding abelian squares is  $4n - 7$  for  $n \geq 3$ . Furthermore, Glen et al. (2009) [3] proved that this length for abelian cubes is  $9n - 13$  for  $n \geq 5$ . They have also conjectured that for any  $k \geq 4$  and sufficiently large  $n$ , the shortest length of a crucial word on  $n$  letters avoiding abelian  $k$ th powers, denoted by  $\ell_k(n)$ , is  $k^2n - (k^2 + k + 1)$ . This is currently the best known upper bound for  $\ell_k(n)$ , and the best known lower bound, provided in Glen et al., is  $3kn - (4k + 1)$  for  $n \geq 5$  and  $k \geq 4$ . In this note, we improve this lower bound by proving that for  $n \geq 2k - 1$ ,  $\ell_k(n) \geq k^2n - (2k^3 - 3k^2 + k + 1)$ ; thus showing that the aforementioned conjecture is true asymptotically (up to a constant term) for growing  $n$ .

## 1. Introduction

Let  $\mathcal{A}_n = \{1, 2, \dots, n\}$  be an  $n$ -letter alphabet and let  $k \geq 2$  be an integer. A word  $W$  over  $\mathcal{A}_n$  contains a  $k$ -th power if  $W$  has a factor of the form  $X^k = XX \cdots X$  ( $k$  times) for some non-empty word  $X$ . For example, the word  $V = 13243232323243$  over  $\mathcal{A}_4$  contains the (non-trivial) fourth power  $(32)^4 = 32323232$ . A word  $W$  contains an *abelian  $k$ -th power* if  $W$  has a factor of the form  $X_1X_2 \cdots X_k$  where  $X_i$  is a permutation of  $X_1$  for  $2 \leq i \leq k$ . The cases  $k = 2$  and  $k = 3$  give us *abelian squares* (introduced by Erdős [1]) and *abelian cubes*, respectively. For instance, the preceding word  $V$  contains the abelian square  $43232 32324$  and the word  $123 312 213$  is an abelian cube. A word  $W$  is (*abelian*)  $k$ -power-free if  $W$  avoids (abelian)  $k$ th powers, i.e., if  $W$  does not contain any (abelian)  $k$ th powers. For example, the word  $1234324$  is abelian cube-free, but not abelian square-free since it contains the abelian square  $234 324$ .

A word  $W$  is *crucial* with respect to a given set of *prohibited words* (or simply *prohibitions*) if  $W$  avoids the prohibitions, but  $Wx$  does not avoid the prohibitions for any letter  $x$  occurring in  $W$ . A *minimal crucial word* is a crucial word of the shortest length. For example, the word  $W = 21211$  (of length 5) is crucial with respect to abelian cubes since it is abelian cube-free and the words  $W1$  and  $W2$  end with the abelian cubes  $111$  and  $21 21 12$ , respectively. Actually,  $W$  is a minimal crucial word over  $\{1, 2\}$  with respect to abelian cubes. Indeed, one can easily verify that there do not exist any crucial abelian cube-free words on two letters of length less than 5.

Let  $\ell_k(n)$  denote the length of a minimal crucial word on  $n$  letters avoiding abelian  $k$ th powers. Evdokimov and Kitaev [2] have shown that  $\ell_2(n) = 4n - 7$  for  $n \geq 3$ . Furthermore, Glen et al. [3] proved that  $\ell_3(n) = 9n - 13$  for  $n \geq 5$ , and  $\ell_3(n) = 2, 5, 11$ , and  $20$  for  $n = 1, 2, 3$ , and  $4$ , respectively. The latter authors also showed that  $\ell_k(n) \leq k^2n - (k^2 + k + 1)$  for  $n \geq 4$  and  $k \geq 3$ , and they made the following conjecture.

**Conjecture 1** ([3]). For any  $k \geq 4$  and sufficiently large  $n$ , we have  $\ell_k(n) = k^2n - (k^2 + k + 1)$ .

The best known lower bound for  $\ell_k(n)$ , provided in [3], is  $3kn - (4k + 1)$  for  $n \geq 5$  and  $k \geq 4$ . The main result of this short note is the following improvement to the foregoing lower bound.

**Theorem 1.** For  $k \geq 2$  and  $n \geq 2k - 1$ ,  $\ell_k(n) \geq k^2n - (2k^3 - 3k^2 + k + 1)$ .

The above theorem shows in particular that **Conjecture 1** is true asymptotically (up to a constant term) for growing  $n$ . Note that for  $k = 2$  the lower bound in **Theorem 1** cannot be improved as it gives the exact value of  $\ell_2(n)$ .

## 2. Proof of Theorem 1

For a crucial word  $X$  (with respect to abelian  $k$ th powers) on the  $n$ -letter alphabet  $\mathcal{A}_n$ , we let  $X = X_i\Delta_i$  where  $\Delta_i$  is the factor of minimal length such that  $\Delta_i$  is an abelian  $k$ th power for  $i \in \mathcal{A}_n$ . Note that we can rename letters, if needed, so we can assume that for any minimal crucial word  $X$ , one has

$$\Delta_1 \subset \Delta_2 \subset \dots \subset \Delta_n = X$$

where “ $\subset$ ” means (proper) right factor (or suffix). In other words, for each  $i = 2, 3, \dots, n$ , we have  $\Delta_i = Y_i\Delta_{i-1}$  for some non-empty  $Y_i$ . In what follows we will use  $X_i$  and  $Y_i$  as stated above. We note that the definitions imply:

$$X = X_i\Delta_i = X_iY_i\Delta_{i-1} = X_{n-1}Y_{n-1}Y_{n-2} \dots Y_2\Delta_1,$$

for any  $i = 2, 3, \dots, n - 1$ . Furthermore, in the case of crucial words avoiding abelian  $k$ th powers, we write  $\Delta_i = \Omega_{i,1}\Omega_{i,2} \dots \Omega_{i,k}$ , where the  $k$  blocks  $\Omega_{i,j}$  are equal up to permutation, and we denote by  $\Omega'_{i,k}$  the block  $\Omega_{i,k}$  without the rightmost  $i$ .

**Lemma 2.** Let  $X = \Omega_{n,1}\Omega_{n,2} \dots \Omega'_{n,k} = Y_nY_{n-1} \dots Y_1$  be a crucial word on  $\mathcal{A}_n$  avoiding abelian  $k$ th powers ( $k \geq 2$ ). For any  $i$ ,  $1 \leq i \leq n - 1$ , if the factor  $Y_{i+1}Y_i$  entirely belongs to the block  $\Omega_{n,j}$  for some  $j$  (possibly  $\Omega'_{n,k}$ ), then the letter  $i$  occurs at least  $k^2$  times in  $X$ .

**Proof.** Since  $\Delta_{i-1}(i - 1)$  and  $\Delta_{i+1}(i + 1)$  are abelian  $k$ th powers (by definition), we deduce that the number of occurrences of the letter  $i$  in each of the factors  $\Delta_{i-1}$  and  $\Delta_{i+1}$  is divisible by  $k$ . Moreover, since  $\Delta_i$  is an abelian  $k$ th power, the number of occurrences of the letter  $i$  in  $\Delta_i$  is  $(k - 1)$  modulo  $k$ , where  $\Delta_i = Y_i\Delta_{i-1}$ . For the preceding statements to hold, the number of occurrences of  $i$  in  $Y_i$  must be at least  $k - 1$ , and hence  $(k - 1)$  modulo  $k$ . Similarly, the number of occurrences of  $i$  in  $Y_{i+1}$  must be at least  $1$ , and hence  $1$  modulo  $k$ . Therefore, the factor  $Y_{i+1}Y_i$  contains at least  $k$  occurrences of the letter  $i$ . Finally, since  $Y_{i+1}Y_i$  is a factor of the block  $\Omega_{n,j}$  for some  $j$  (by hypothesis) and  $Xn = \Omega_{n,1}\Omega_{n,2} \dots \Omega'_{n,k}n$  is an abelian  $k$ th power, we conclude that  $i$  occurs at least  $k^2$  times in  $X$ .  $\square$

**Proof of Theorem 1.** Let  $X = \Omega_{n,1}\Omega_{n,2} \dots \Omega'_{n,k} = Y_nY_{n-1} \dots Y_1$  be a crucial word on  $\mathcal{A}_n$  avoiding abelian  $k$ th powers ( $k \geq 2$ ). As an obvious corollary to **Lemma 2**, one has that if the factor  $Y_{i+1}Y_i \dots Y_t$  entirely belongs to the block  $\Omega_{n,j}$  for some  $j$ , then each of the letters  $t, t + 1, \dots, i$  must occur at least  $k^2$  times in  $X$ . Thus, out of all  $Y_i$ 's entirely belonging to a single block  $\Omega_{n,j}$  only one of them can correspond to a letter occurring less than  $k^2$  times in  $X$ , which gives in total at most  $k$  such letters. Additionally, at most  $k - 1$   $Y_i$ 's cannot be inside a single block  $\Omega_{n,j}$ , and theoretically the letters corresponding to such  $Y_i$ 's could occur less than  $k^2$  times in  $X$  (we have no information on such  $Y_i$ 's). To summarize,  $X$  would have the minimal possible number of letters if  $X$  was of the form

$$X = Y_nZ_nY_{i_1}Y_{i_1-1}Z_{n-1}Y_{i_2}Y_{i_2-1} \dots Y_{i_{k-1}}Y_{i_{k-1}-1}Z_1,$$

where factor  $Z_i$  entirely belongs to one of  $k - 1$  blocks  $\Omega_{n,j}$ , or the block  $\Omega'_{n,k}$ . Moreover,  $Y_n, Y_{i_1-1}, Y_{i_2-1}, \dots, Y_{i_{k-1}-1}$  are the leftmost factors entirely inside the corresponding blocks  $\Omega_{n,j}$  or  $\Omega'_{n,k}$ ;  $Y_{i_1}, Y_{i_2}, \dots, Y_{i_{k-2}}$  are factors having letters in two adjacent blocks  $\Omega_{n,j}$  and  $\Omega_{n,j-1}$  for some  $j$ ; and the factor  $Y_{i_{k-1}}$  has letters in both  $\Omega_{n,k-1}$  and  $\Omega'_{n,k}$ . All of the  $2k - 1$  factors  $Y_i$  in the above decomposition correspond to letters occurring  $k$  times, whilst any other letter must occur at least  $k^2$  times. Thus, for  $n \geq 2k - 1$ , the length of  $X$  is bounded from below by

$$k^2(n - (2k - 1)) + (2k - 1)k - 1 = k^2n - (2k^3 - 3k^2 + k + 1),$$

where the term  $(2k - 1)k - 1$  comes from the fact that each letter out of those occurring less than  $k^2$  times in  $X$  occurs at least  $k$  times there, except for the letter  $n$  which may occur only  $k - 1$  times.  $\square$

### 3. Further discussion

Even though the goal of this short paper was to prove an “asymptotic version” of [Conjecture 1](#) (rather than attempting to prove the conjecture itself or improving our lower bound as much as possible), we would like to share some ideas that may be helpful for further study of crucial words avoiding abelian powers, particularly with regards to proving/disproving [Conjecture 1](#) or improving the lower bound in [Theorem 1](#).

In our considerations here (and in [3]), we do not use the fact that crucial words avoid abelian powers. Thus, it is natural to study what we call *weakly crucial words* with respect to abelian powers (or other prohibitions); namely words that may contain abelian powers, but extending these words to the right by any letter  $x$  occurring within them creates an abelian power involving the rightmost  $x$ . For weakly crucial words, one has a nice hereditary property that erasing any letter in such a word gives a weakly crucial word. In particular, to prove lower bounds for the length of (regular) crucial words with respect to abelian  $k$ th powers, one could start by erasing all the letters occurring more than  $k^2$  times, thus obtaining a weakly crucial word, and then work only with letters occurring less than  $k^2$  times (the number of such letters, due to the proof of [Theorem 1](#), is at most  $2k - 1$ ). It is likely that the best lower bounds for the lengths of weakly crucial words and regular crucial words with respect to abelian  $k$ th powers coincide.

Our final remark is as follows. Assuming the following conjecture is true, the lower bound in [Theorem 1](#) would be significantly improved to  $k^2(n - 3) + 3k - 1 = k^2n - (3k^2 - 3k + 1)$ .

**Conjecture 2.** For a (weakly) crucial word  $X = Y_n Y_{n-1} \cdots Y_1$  on  $\mathcal{A}_n$  avoiding abelian  $k$ th powers ( $k \geq 2$ ), there cannot exist 3 letters less than  $n$  that occur less than  $k^2$  times in  $X$ .
